

# Movement of Materials through the Cell Membrane

## Cell Transport

### I. Passive transport

Movement of molecules of a solute from areas of high to low concentration **without the use of energy**

## Types of Passive Transport

### 1. diffusion:

- movement of molecules **other than H<sub>2</sub>O** from areas of high to low concentration until equilibrium is reached
- **equilibrium**: steady state where equal numbers of molecules move in each direction
- **concentration gradient**: differences in concentration of a substance across a space

### 2. Osmosis

- movement of **water** from areas of high to low concentration until equilibrium is reached
- direction of movement depends on **CONCENTRATION OF WATER** on either side of the concentration gradient

## Types of osmotic solutions

- hypotonic
- hypertonic
- isotonic

indicates relative concentration of two solutions being compared

OSMOTIC CONDITIONS			
TYPE OF SOLUTION	CONCENTRATION INSIDE CELL	CONCENTRATION OUTSIDE CELL	DIRECTION OF WATER MOVEMENT
HYPOTONIC	LESS WATER	MORE WATER	INTO CELL
HYPERTONIC	MORE WATER	LESS WATER	OUT OF CELL
ISOTONIC	EQUAL WATER	EQUAL WATER	IN & OUT OF CELL AT SAME RATE

### SOLUTIONS IN CELLS

### PLANT CELL

Results of water transport in and out of cells:

### Animal Cells

- Hypertonic**: crenation
- Hypotonic**: cytolysis

### Plant cells

- Hypertonic**: plasmolysis
- Hypotonic**: turgor pressure

### Plant cell adaptations:

**Cell wall**: limits amount of water into cell

**Contractile vacuole**: rhythmically pumps water out of cell (unicellular org.)

### 3. facilitated diffusion

- movement of a substance from areas of high to low concentration with the aid of a carrier protein (driven by diffusion)
- type of passive transport (**no energy used**)

ex: glucose into a RBC

## Steps of Facilitated Diffusion

1. carrier protein binds a specific molecule on one side of membrane
2. change in shape of carrier protein exposes one molecule to other
3. carrier protein shields the molecule from interior of lipid bilayer
4. molecule is released from carrier protein which goes back to original shape

## II. Active transport

- movement of substances through a membrane against (up) a concentration gradient
- requires energy (from ATP)

Carrier proteins are used in active transport to pick up ions or molecules from near the cell membrane, carry them across the membrane, and release them on the other side. Active transport requires energy.

## 2 types active transport

### 1. membrane pumps

- involves carrier proteins which act as pumps
- ions in lower concentration bind to carrier protein and are released to areas of higher concentration (Ca<sup>+</sup>, K<sup>+</sup>, Na<sup>+</sup>, others)

ex: sodium potassium pump

### 2. endocytosis/exocytosis

#### Endocytosis

process where cells engulf substances too large to enter by passing through membrane

#### Types

- **phagocytosis**: solid particles
- **pinocytosis**: liquid substances

#### Exocytosis

- process of removing large substances out of cell (opposite mechanism of endocytosis)
- Ex: cells manufacture proteins – vesicles fuse with cell membrane and dump contents out of cell
- removal of cell debris, bacteria/viruses, old organelles

[animation](#)

## Cell Specialization

- Cells have special structures/ shapes to perform a specific function
